PATENT APPLICATION

THERMOLUMINESCENCE DOSIMETERS WITH NARROW BANDPASS FILTERS

5

GOVERNMENT RIGHTS

The Government has rights to this invention pursuant to Contract No. DE-AC04-94AL85000 awarded by the U.S. Department of Energy.

BACKGROUND OF THE INVENTION

10

Field of the Invention (Technical Field):

The present invention relates to thermoluminescence dosimeters (TLDs) for radiation dosimetry.

Background Art:

15

Current dosimetry methods employ TLDs that have materials such as copper, mylar, tin, and/or plastics placed over them to filter the radiation energy. See, e.g., M. Moscovitch, et al., "Mixed Field Personnel Dosimetry Using a Nearly Tissue-Equivalent Multi-Element Thermoluminescence Dosimeter", *Radiation Protection Dosimetry* 34:1/4, pp. 145-148 (1990); and T.F.L. Daltro, et al.,

20

"Thermoluminescence Dosimeter for Equivalent Dose Assessment in Mixed Beta and Gamma Field", *Radiation Protection Dosimetry* 85:1-4, pp. 145-148 (1999). This radiation filtration causes varying

25

degrees of energy to be absorbed by the TLD material underneath the filter(s). These dosimeters are processed using machines such as the Model 8800PC reader manufactured by Bicron/NE of Solon, Ohio. K.J. Velbeck, et al., "Next Generation Model 8800 Automatic TLD Reader", *Radiation Protection Dosimetry* 84:1-4, pp. 381-386 (1999). Dose calculation algorithms attempt to determine radiation type and energy based solely on the ratios of light output without regard to the light wavelength. See, e.g., E.W. Bradley, et al., "Harshaw Dose Calculation Algorithm", Sandia National Laboratories Report (1994); Daltro, et al., *supra*; and Moscovitch, et al., *supra*. Additionally, the use of radiation filters creates an angular dependence problem that results in an underestimation of the dose equivalent when a worker is

not directly facing the radiation source. L.F. Friedman, et al., "Angular Dependence of the Harshaw 8800/8812 TLD System", Sandia National Laboratories Report (1991).

TLDs operate in the following manner. Electrons within a material normally exist at an energy level known as the valence band. Through some outside physical processes, such as heating or, in the present case, a radiation event, these electrons can be excited into another region known as the conduction band. The electrons are free to move around in the conduction band, but they will always attempt to return to their ground state. Since energy must be conserved in such a transition, the crystal emits light photons that escape the material. The light is the medium that is used to create the correlation between absorbed energy and dose equivalent for an individual. However, once the light is emitted, all information about the radiation event(s) is lost. Therefore, a method must be used to trap the electron(s) in place until the dosimeter is ready to be processed.

Between the valence and conduction bands exists an area known as the forbidden region. Electrons in a material cannot exist in this region unless they are trapped there by an impurity when they attempt to return to their ground state. After being trapped, return to ground then occurs when the TLD reader heats the TLD with hot nitrogen gas, which causes the emission of photons of particular wavelengths. For dosimetry purposes, these impurities are purposely added to the TLD crystal and are referred to as dopants. For example, the present dosimeter employed by Sandia National Laboratories uses LiF that is doped with magnesium and titanium to create electron capture sites within a forbidden energy region of the crystal. For LiF:Mg,Ti, this region exists between 2.076-3.550 eV and will correspond to a light wavelength emission of 350-600 nm during dosimeter processing by the reader. Since current methods use the entire wavelength of light from the LiF, they depend totally on the dose calculation algorithm to make determinations about radiation type and energy.

A TLD crystal using LiF doped with magnesium, copper, and phosphorus (LiF:Mg,Cu,P) has recently been developed that appears to provide higher sensitivity than TLDs using Li:Mg,Ti. M. Moscovitch, "Personnel Dosimetry Using LiF:Mg,Cu,P", *Radiation Protection Dosimetry* 85:1-4, pp. 49-

5 The present invention provides an improved thermoluminescence dosimetry method, TLD, and TLD lens drawer that allows dosimetrists to more accurately determine what type of radiation and energy an individual or physical environment has been exposed to during a monitoring period. And, having the knowledge of these conditions, he or she will also be able to more accurately calculate the dose equivalent received by the worker or environment.

Objects, advantages and novel features, and further scope of applicability of the present invention will be set forth in part in the detailed description to follow, taken in conjunction with the accompanying drawings, and in part will become apparent to those skilled in the art upon examination of the following, or may be learned by practice of the invention. The objects and advantages of the invention may be realized and attained by means of the instrumentalities and combinations particularly pointed out in the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated into and form a part of the specification, illustrate one or more embodiments of the present invention and, together with the description, serve to explain the principles of the invention. The drawings are only for the purpose of illustrating one or more preferred embodiments of the invention and are not to be construed as limiting the invention. In the drawings:

Fig. 1 is a top view of the preferred TLD lens drawer of the invention; and

Fig. 2 is a top view of the sensitive element of a TLD (prior art).

DESCRIPTION OF THE PREFERRED EMBODIMENTS

(BEST MODES FOR CARRYING OUT THE INVENTION)

The present invention is of an improved dosimetry method, TLD lens drawer, and thermoluminescence dosimeter (TLD), such as those employing the lithium-fluoride (LiF) crystals (chips) discussed above. Such TLDs are processed by a TLD reader such as the Model 8800PC hot nitrogen gas reader described above. In the present invention, light output from the dosimeters is screened using bandpass filters and processed using the normal reader functionality to establish a plurality (preferably four) of discrete ranges of light wavelengths, such as four non-overlapping ranges in the range of 350-600 nanometers for LiF TLDs. The amount and ratios of the various light wavelengths are then correlated to radiation type and energy. Based on knowledge of the incident radiation type and energy, a

dose calculation is then be made using an appropriate dose calculation algorithm, as understood and readily developable by one of ordinary skill in the art.

The present invention is technically different from current methods for calculating doses because the TLD (such as LiF) crystal itself already possesses the necessary information regarding the radiation energy, radiation type, and penetrability. It is this crucial information that is lost during processing using current means. The present invention establishes the radiation type and energy using the relationship

$$\lambda = \frac{hc}{E},$$

where λ is the wavelength of the light emission, h is Planck's constant, c is the speed of light, and E is the energy of the emitted light photon. Since E is directly related to the depth of the electron trap within the dosimeter crystal, knowledge of the wavelength of the light emission will yield knowledge of the incident radiation type and energy that can be directly related to dose depth in human tissue. With the present invention, this determination can be done without the expensive and cumbersome filters inherent to current dosimeters, significantly reducing if not eliminating altogether the angular dependence problem.

The present invention results in a profound improvement in the dose calculations that are performed for radiological workers. The improvement results not only from the method used to determine the radiation type and energy, but also from a reduction in the angular dependence that is so prevalent in current dosimeter designs. The present invention also results in significant cost savings for dosimeters because they no longer require elaborate holders with various filter combinations that cost anywhere from \$8-\$12 apiece.

Fig. 1 illustrates in top view the preferred embodiment of the improved lens drawer **10** of the invention which is incorporated into prior art TLDs. In the prior art, the lens drawer comprises one or

more (such as four) of clear lenses that pass all light wavelengths but provide physical protection of the photomultiplier tubes of the TLD reader from environmental degradation, such as from deposits of foreign matter previously deposited on the TLD. In the invention, the lens drawer comprises one or more (such as four) bandpass filters **12** (preferably lenses) that each allow only predetermined wavelengths to pass to the TLD crystal beneath. Each bandpass filter filters a wavelength range that may or may not overlap that of the other bandpass filters. The range width of each bandpass filter can be between, for example, approximately 25nm and 100nm.

Fig. 2 illustrates the sensitive element **16** of a TLD (prior art), comprising one or more TLD crystals **14** (typically encapsulated in teflon) which correspond in number to the number of lenses in the lens drawer, identification barcode **18**, and aluminum card **20**. The present invention does not alter the design of the sensitive element of the TLD, although thicknesses, materials, and doping of the TLD crystals can be altered to take advantage of the wavelength filtration provided by the improved lens drawer of the invention.

Although the invention has been described in detail with particular reference to these preferred embodiments, other embodiments can achieve the same results. Variations and modifications of the present invention will be obvious to those skilled in the art and it is intended to cover in the appended claims all such modifications and equivalents. The entire disclosures of all references, applications, patents, and publications cited above are hereby incorporated by reference.
